Suggested Variable Naming Conventions in the Econ-ARK Toolkit

2026-10-22

Abstract

Sharing code is easier when different contributors use similar names for similar objects. While we will not enforce the recommendations below, contributors can make their code more attractive to others by using names consistent with our guidelines.

Keywords ARK, Variable, Function, Object, Operator, Naming, Guidelines, Conventions

JEL codes None

1 Principles

Our aim has been to balance:

- Brevity
- Mnemonicity
- Uniqueness (enabling global search-and-replace)
- Ubiquity (definitions useful for many projects)
- Combinatoriality (which encourages mashups)

The symbols in this document follow version 6.0.0 of the Econ-ARK notation registry, which is maintained in the `econ-ark-tools` repository and copied into this one under `@resources/notation`.

2 Variables

2.1 Single-Letter

We strongly discourage the use of single-letter variable names. Reasons are presented *ad nauseam* in introductory CS texts (which, we know, few economists consult); here we will note only that the extent to which your code will be influential depends upon the extent to which someone else can easily read it, which is harder if you have used variable names which could mean almost anything. (We have made careful choices for the 'default' meanings of each Roman letter (see below); hence, in the context of the toolkit, use of a single-letter name for any meaning other than the designated one will be doubly confusing).

It is only slightly less objectionable to name a variable after a familiar letter in another commonly used alphabet (say, `delta`). Your future self (and other users) will not know which of the many possible meanings of δ you had in mind.

But, because brevity is a virtue, a single letter *in combination with a modifier or two* ('`hMin`' as the value of minimum human wealth, say) is fine – so long as the reader has some reason to expect that the lower-case letter `h` signifies human wealth (as they will, if they consult Table 1).

That is the spirit in which we offer preferred interpretations for the Roman letters below. The upper case version is an aggregated version of the variable (at the level of the whole economy, say, or of the whole market being studied), while the lower case indicates the level of an individual consumer or firm or other subaggregate entity.

A few exceptions to these rules are explicitly noted below the table.

When an alternative is needed with a meaning similar to, but distinct from, the definitions below, please use a multi-letter name to represent it. For example, please do not use W for wealth (if some measure of wealth that differs from $\boldsymbol{A}$, $\boldsymbol{B}$, $\boldsymbol{H}$, or O is needed); instead use, say, `Wlth` or `Wealth`. (Some examples follow in a subsequent section).

Finally, a few of the definitions below are actually prohibitions; these are based on many years of experience which have shown that use of the prohibited variable name generates more confusion than clarity.

2.2 Exceptions to the Rules

The letter $\boldsymbol{T}$ is an exception to the rule that lower- and upper-case versions of variables are individual and aggregate quantities. We reserve the capital letter to designate the end of the horizon (death, or the end of the economy, occurs at the end of period $\boldsymbol{T}$). The lower case version t is so ubiquitously used as the current time period that we follow that convention here.

The letter O was prohibited because it is too similar to the number 0. The prohibition is lifted for total wealth, nonhuman plus human: $o = b + h$ for an individual, and O for the aggregate.

Letter	Meaning
A	*A*ssets *A*fter *A*ll *A*ctions *A*re *A*ccomplished (end of period)
B	*B*ank *B*alances *B*efore any *B*ehavior (*b*eginning-of-period)
C	*C*onsumption *C*hoice *C*onnects B to A
D	*D*ebt
E	PROHIBITED: Too many possible meanings (expectations, effort, expenses)
F	Production *F*unction
G	*G*rowth
H	*H*uman wealth
I	*I*nvestment
J	Ad*J*ustment costs (e.g., in a Q model)
K	Capital or beginning of period nonhuman assets
L	PROHIBITED: Is it Labor or Leisure or Land or ...?
M	*M*arket resources (the sum of capital, capital income, and labor income)
N	*N*et wealth including human wealth ($= B + H$): now O (see the exceptions)
O	*O*verall wealth ($O = B + H$); see the exceptions
P	PROHIBITED: Is it prices, permanent income, present value, profits, ...?
Q	Hayashi/Abel Q (or similar asset price)
R	*R*eturn (see the variants articulated below)
S	PROHIBITED: "saving" (flow)? "savings" (stock)? or the "saving rate" (ratio)?
T	This is a tough one. See the discussion below.
U	*U*tility
V	*V*alue
W	*W*age
X	e*X*penditures, as distinct from consumption; see the exceptions
Y	Noncapital income (usually, the sum of transfer and labor income)
Z	Lei*Z*ure in consumption/leisure tradeoff

Table 1 Preferred Usages of Roman Letters

The capital X keeps its meaning, expenditures, and is an exception to the case rule: it is not the aggregate of a lower-case x.

A prohibition covers only the plain letter. Other fonts of a prohibited letter remain available, and several are in use: $\mathbb{P}$ for present discounted value, $\mathbb{E}$ for expectations, $\mathcal{L}$ for the probability of survival, and ℓ for labor. Likewise the sans-serif D for the probability of death does not collide with D for debt.

Finally, the following are exempted from the prohibition on single-letter variable names because they are used so frequently that the prohibition would be more trouble than it is worth: a, b, c, m.

2.3 Standard Variable Names

There are more objects that are likely to be used extensively in ARK projects than there are Roman letters. We present preferred usages for some of those commonly-needed variables here.

Name	-	Description
`CND`	-	Consumption of Nondurable Good
`CNS`	-	Consumption of Nondurables and Services
`Cst`	-	Cost of something
`Dgd`	-	Stock of durable good
`Dvd`	-	Dividends
`Hse`	-	Quantity of housing (*not* value, which is quantity $\times$ price)
`Inc`	-	Income
`Nlq`	-	Quantity that is **N**ot **liq**uid (e.g., `aNlq` is illiquid financial)
`Lbr`	-	Quantity of labor (hours)
`Pop`	-	Size of population
`Sav`	-	Saving (=Income Minus Consumption)
`Tax`	-	Tax – should be modified by `Rte` or `Amt` articulated below
`Perm`	-	Permanent (labor; or at least, noncapital) income
`Tran`	-	Transitory (labor; or at least, noncapital) income

Table 2 String Variables

3 Factors and Rates

When measuring change over time, lower-case variables reflect rates while the corresponding upper-case variable connects adjacent discrete periods.[1,2] So, for example, if the time interval is a year and the annual interest rate is $\mathsf{r} = 0.03$ or three percent, then the annual interest factor is $\mathsf{R} = 1.03$.[3]

We depart from the upper-lower case scheme when the natural letter to use has an even more urgent use elsewhere in our scheme. A particularly common example occurs in the case of models like Blanchard (1985) in which individual agents are subject to a Poisson probability of death. We write the probability of death as a sans-serif D or, alternatively, as a cancelled probability of survival:

[1] This convention rarely conflicts with the usage we endorse elsewhere of indicating individual-level variables by the lower and aggregate variables by the upper case.

[2] If there is a need for the continuous-time representation, we endorse use of the discrete-time rate defined below. Any author who needs a continuous-time rate, a discrete-time rate, and a discrete-time factor is invited to invent their own notation.

[3] In the rare cases where it is necessary to distinguish between a continuous-time rate and a discrete-time rate – for example, when there is an analytical result available in continuous time – the variable in question can be modified by `Cnt` or `Dsc`.

Code	Output	Description
\Rfree	R	Riskfree interest factor
\rfree	r	Riskfree interest rate
\Risky	$\mathbf{R}$	The return factor on a risky asset
\risky	$\mathbf{r}$	The return rate on a risky asset
\Rport	$\mathfrak{R}$	The return factor on the entire portfolio
\rport	$\mathfrak{r}$	The return rate on the entire portfolio
\RSave	$\underline{\mathsf{R}}$	Return factor earned on positive end-of-period assets
\rsave	$\underline{\mathsf{r}}$	Return rate earned on positive end-of-period assets
\RBoro	$\bar{\mathsf{R}}$	Return factor paid on debts
\rboro	$\bar{\mathsf{r}}$	Return rate paid on debts

Table 3 Factors and Rates

Code	LaTeX	Description	Definition
\DiePrb	D or $\mathscr{L}$	Probability of death	$\mathsf{D} = 1 - \mathcal{L}$
\LivPrb	$\mathcal{L}$	Probability of survival (also \Alive)	$\mathcal{L} = 1 - \mathsf{D}$
\RfreeEff	$\mathring{\mathsf{R}}$	Return factor for a survivor	$\mathring{\mathsf{R}} = \mathsf{R}/\mathcal{L}$
\DiscFacEff	$\mathring{\beta}$	Discount factor including survival	$\mathring{\beta} = \beta\mathcal{L}$
\APFacEff	$\mathring{\mathbf{P}}$	Absolute Patience Factor including survival	$\mathring{\mathbf{P}} = (\mathsf{R}\mathring{\beta})^{1/\varrho}$
\RPFacEff	$\mathring{\mathbf{P}}_{\mathsf{R}}$	Return Patience Factor including survival	$\mathring{\mathbf{P}}_{\mathsf{R}} = \mathring{\mathbf{P}}/\mathsf{R}$
\GPFacEff	$\mathring{\mathbf{P}}_{\mathcal{G}}$	Growth Patience Factor including survival	$\mathring{\mathbf{P}}_{\mathcal{G}} = \mathring{\mathbf{P}}/\mathcal{G}$
\GPFacLiv	$\mathcal{L}\mathring{\mathbf{P}}_{\mathcal{G}}$	Mortality-adjusted Growth Patience Factor	$\mathcal{L}\mathring{\mathbf{P}}_{\mathcal{G}} = \mathcal{L}\mathring{\mathbf{P}}/\mathcal{G}$

Table 4 Survival

A ring marks the version of a factor that includes survival: β and $\mathbf{P}$ without the ring exclude it. The mortality-adjusted growth impatience condition (GIC-Liv) is $\mathcal{L}\mathring{\mathbf{P}}_{\mathcal{G}} < 1$, where $\mathcal{L}\mathring{\mathbf{P}}_{\mathcal{G}}$ is $\mathcal{L}$ times $\mathring{\mathbf{P}}_{\mathcal{G}}$. In HARK's code `DiscFacEff` is $\mathring{\beta}$, and the patience factors `APFac`, `RPFac` and `GPFacRaw` already include survival: they are $\mathring{\mathbf{P}}$, $\mathring{\mathbf{P}}_{\mathsf{R}}$ and $\mathring{\mathbf{P}}_{\mathcal{G}}$, not $\mathbf{P}$, $\mathbf{P}_{\mathsf{R}}$ and $\mathbf{P}_{\mathcal{G}}$.

4 Parameters

Some parameters are worth defining because they are likely to be used in a high proportion of models; others are subject to enough constraints when used (such as the need for similar-looking upper- and lower-case Greek representations), as to be worth standardizing.

Programmers should use the corresponding variable name without the backslash as the name of the corresponding object in their code. For example, the Coefficient of Relative Risk Aversion is \CRRA in a LaTeX document and `CRRA` in a software module.

The individual transitory shock ξ includes any zero-income event, so \tranShkAll is another name for the same object. With probability $\wp$ the consumer is unemployed and

$\xi = \xi_{\text{U}}$; otherwise $\xi = \theta(1-\wp\xi_{\text{U}})/(1-\wp)$, where θ is the employed draw, so $\mathbb{E}[\xi] = 1$. In HARK's code $\wp$ is `UnempPrb`. Θ is the aggregate of θ (`\TranShkEmp` is another name for it); ξ has no aggregate. The population growth rate has no letter of its own: because ξ is the transitory shock, it is written $\ln \Xi$.

Mnemonics:

- Hebrew `daleth` is the fourth letter of the Hebrew alphabet (as d and δ are of the Roman and Greek) and is an etymological and linguistic cousin of those letters
- ν is the lower case Greek letter `nu`, because newness is about the future
- You are invited to scrutinize Ξ yourself to imagine reasons it could represent something to do with population growth.
- The glorious letter **Þ** (pronounced 'thorn') enriched Old English, Gothic, and some other defunct alphabets; sadly, it remains in use today only in Iceland. It is useful because having to type the many symbols in the object $(\mathsf{R}\beta)^{1/\varrho}$ over and over again is a *thorn* in the side of economists working with dynamic models! (It is the 'absolute patience factor' because if it is less than one the consumer wants to bring resources from the future to the present and is therefore absolutely impatient; for a fuller discussion of this terminology, see Carroll (2016).)

5 Operators

A few operators are so universally used that it will be useful to define them.

6 Modifiers

Shocks will generally be represented by finite vectors of outcomes and their probabilities. For example, permanent income is called `Perm` and shocks are designated `PermShk`

Periods are named relative to the current period t: `Prev`, `Now` and `Nxt` are the periods $t-1$, t and $t+1$, as in the notation registry's `\Now` and `\Nxt`. Because `Prev` names the previous period, steps within a period no longer have reserved words.

7 Model Imports

A convention in python is that when a tool is imported it is given a convenient short name, e.g. `import numpy as np`.

Here are the preferred shortnames for some of our models:

```
import ConsIndShockModel as cisMdl
```

Name	LaTeX	Description	Illustration
\CARA	cara	Coefficient of Absolute Risk Aversion	$\mathrm{u}(\bullet) = -\mathrm{cara}^{-1}e^{-\mathrm{cara}\bullet}$
\CRRA	ϱ	Coefficient of Relative Risk Aversion	$\mathrm{u}(\bullet) = (1-\varrho)^{-1}\bullet^{1-\varrho}$
\DiscFac	β	Time Discount Factor	$\mathrm{u}'(\boldsymbol{c}_t) = \mathsf{R}\beta\mathrm{u}'(\boldsymbol{c}_{t+1})$
\discRte	ν	Time Discount rate	$\nu = \beta^{-1} - 1$
\DeprFac	$\daleth$	Depreciation Factor (Hebrew daleth)	$K_{t+1} = \daleth K_t + \boldsymbol{I}_t$
\deprRte	δ	Depreciation Rate	$\daleth = 1 - \delta$
\kapShare	α	Capital share, Cobb-Douglas production	$F(K,\ell) = K^{\alpha}\ell^{1-\alpha}$
\labor	ℓ	Labor (or labor productivity)	$W\ell$ is labor income
\TranShkAgg	Θ	Transitory shock (aggregate of θ)	$\mathbb{E}_t[\Theta_{t+n}] = 1$ if Θ iid
\tranShkInd	ξ	Transitory shock (individual)	$\mathbb{E}_t[\xi_{t+n}] = 1$ if ξ iid
\tranShkEmp	θ	Transitory shock (individual, employed)	$\mathbb{E}_t[\theta_{t+n}] = 1$ if θ iid
\pZero	$\wp$	Probability of unemployment	$\Pr(\xi = \xi_{\mathrm{U}}) = \wp$
\PermShkAgg	Ψ	Permanent shock (aggregate)	$\mathbb{E}_t[\Psi_{t+n}] = 1$ if Ψ iid
\permShkInd	ψ	Permanent shock (individual)	$\mathbb{E}_t[\psi_{t+n}] = 1$ if ψ iid
\PopGroFac	Ξ	Population Growth Factor	$\mathtt{Pop}_{t+1} = \Xi\mathtt{Pop}_t$
\popGroRte	$\ln\Xi$	Population Growth rate	$\ln\Xi \approx \Xi - 1$
\PtyGroFac	G	Productivity Growth Factor	$\boldsymbol{Y}_{t+1}/\boldsymbol{Y}_t = \mathsf{G}\Xi$
\ptyGroRte	g	Productivity Growth rate	$\mathsf{G} = (1+\mathsf{g})$
\leiShare	ζ	Leisure share, Cobb-Douglas utility	$\mathrm{u}(c,z) = (1-\varrho)^{-1}(c^{1-\zeta}z^{\zeta})^{1-\varrho}$
\MPC	κ	Marginal Propensity to Consume	$\mathrm{c}^m(m) = \partial c/\partial m$
\APFac	$\mathbf{Þ}$	Absolute Patience Factor (Thorn)	$\mathbf{Þ} = (\mathsf{R}\beta)^{1/\varrho}$
\APRte	þ	Absolute Patience rate (thorn)	$þ = \log\mathbf{Þ} \approx \varrho^{-1}(\mathsf{r}-\nu)$
\GPFac	$\mathbf{Þ}_{\mathcal{G}}$	Growth Patience Factor (Thorn/$\mathcal{G}$)	$\mathbf{Þ}_{\mathcal{G}} = \mathbf{Þ}/\mathcal{G}$
\GPRte	$þ_g$	Growth Patience rate (thorn$-g$)	$þ_g \approx þ - g$
\RPFac	$\mathbf{Þ}_{\mathsf{R}}$	Return Patience Factor (Thorn/R)	$\mathbf{Þ}_{\mathsf{R}} = \mathbf{Þ}/\mathsf{R}$
\RPRte	$þ_{\mathsf{r}}$	Return Patience rate (thorn$-$r)	$þ_{\mathsf{r}} \approx þ - \mathsf{r}$
\riskyshare	ς	Portfolio share in risky assets	$\mathfrak{R}_{t+1} = (1-\varsigma)\mathsf{R} + \varsigma\mathbf{R}_{t+1}$
\eprem	ϕ	Log equity premium	$\phi = \mathbb{E}[\log\mathbf{R}] - \log\mathsf{R}$
\DiscFacSprd	∇	Spread of discount factors	
\paretoExp	ε	Pareto exponent of wealth	$\Pr(\mathrm{wealth} > \bullet) \propto \bullet^{-\varepsilon}$
\weight	ω	A weight (mass, probability, mixture)	$\sum_i \omega_i = 1$

Table 5 Parameters

Name	LaTeX	Code	Description	Illustration
\Ex	$\mathbb{E}$	Ex_	The expectation as of date t	$\mathbb{E}_t[\mathrm{u}'(c_{t+1})]$
\PDV	$\mathbb{P}$	PDV_	Present Discounted Value	$\mathbb{P}_t^T(y)$ is human wealth

Table 6 Operators

[object]`Agg`	-	Value of something at the aggregate level (as opposed to `Ind`)
[object]`Ind`	-	Value of something at the level of an individual (as opposed to `Agg`)
[object]`Lvl`	-	Level
[object]`Rto`	-	Ratio
[object]`Bot`	-	Lower value in some range
[object]`Top`	-	Upper value in some range
[object]`Min`	-	Minimum possible value
[object]`Max`	-	Maximum possible value
[object]`Cnt`	-	Continuous-time value
[object]`Dsc`	-	Discrete-time value
[object]`Shk`	-	Shock
[object]`StE`	-	Steady-state Equilibrium value of a variable
[object]`Trg`	-	The 'target' value of a variable
[object]`Rte`	-	A 'rate' variable like the discount rate ν
[object]`Fac`	-	A factor variable like the discount factor β
[object]`Amt`	-	An amount, like `TaxAmt` which might be lump-sum
[object]`Nrm`	-	A normalized quantity; ex: `RNrmByG`=$\mathcal{R} = \mathsf{R}/\mathcal{G}$
[object]`Abve`	-	Range of points ABoVE some boundary
[object]`Belw`	-	Range of points BELoW some boundary
[object]`Grid`	-	Points to be used as a grid for interpolations
[object]`Xtra`	-	An "extra" set of points to be added to some existing set

Table 7 General Purpose Modifiers

[object]`Dstn`	-	Representation of a probability distribution (includes both Prbs and Vals)
[object]`Prbs`	-	Probabilities of outcomes (e.g. `PermShkPrbs` for permanent shocks)
[object]`Vals`	-	Values (e.g., for mean one shock `PermShkVals` . `PermShkPrbs` = 1)

Table 8 Probabilities

[object]`tmn`	-	object in period t minus n
[object]`Prev`	-	object in period $t-1$
[object]`Now`	-	object in period t
[object]`t`	-	object in period t (alternative definition)
[object]`Nxt`	-	object in period $t+1$
[object]`tpn`	-	object in period t plus n

Table 9 Timing
